Abstract. The abstract should briefly summarize the contents of the paper in 150–250 words.

Keywords: Linear arithmetic \cdot SMT \cdot normal form \cdot Lambdapi \cdot reflection

1 Alethe proof

The Alethe proof trace format [2] for SMT solvers comprises two parts: the trace language based on SMT-LIB and a collection of proof rules. Traces witness proofs of unsatisfiability of a set of constraints. They are sequences $a_1 \dots a_m \ t_1 \dots t_n$ where the a_i corresponds to the constraints of the original SMT problem being refuted, each t_i is a clause inferred from previous elements of the sequence, and t_n is \bot (the empty clause). In the following, we designate the SMT-LIB problem as the *input problem*.

```
1 (set-logic QF_LIA)
2 (declare-const x Int)
3 (declare-const y Int)
4 (assert (= 0 y))
5 (assert (= x 2))
6 (assert (or (< (+ x y) 1) (< 3 x)))
7 (get-proof)
```

4

```
1 (assume a0 (or (< (+ x y) 1) (< 3 x)))
2 (assume a1 (= x 2))
3 (assume a2 (= 0 y))
4 (step t1 (c1 (< (+ x y) 1) (< 3 x)) :rule or :premises (a0))
5 (step t2 (c1 (not (< 3 x)) (not (= x 2))) :rule la_generic :args (1/1 1/1))
6 (step t3 (c1 (not (< 3 x))) :rule resolution :premises (a1 t2))
7 (step t4 (c1 (< (+ x y) 1)) :rule resolution :premises (t1 t3))
8 (step t5 (c1 (not (< (+ x y) 1)) (not (= x 2)) (not (= 0 y))) :rule la_generic :args (1/1 -1/1 1/1))
9 (step t6 (c1) :rule resolution :premises (t5 t4 a1 a2))
```

Listing 1.1. The following example is the proof for the unsatisfiability of $(x + y < 1) \lor (3 < x), x = 2$ and 0 = y.

We will use the input problem shown in the top part of example 1 with its Alethe proof (found by cvc5) in the bottom part as a running example to provide an overview of Alethe concepts and to illustrate our reconstruction of linear arithmetic step in Lambdapi.

1.1 Alethe Trace Format Overview

An Alethe proof trace inherits the declarations of its input problem. All symbols (sorts, functions, assertions, etc.) declared or defined in the input problem remain declared or defined, respectively. Furthermore, the syntax for terms, sorts, and annotations uses the syntactic rules defined in SMT-LIB [3, §3] and the SMT signature context defined in [3, §5.1 and §5.2]. In the following we will represent an Alethe step as

A step consists of an index $i \in \mathbb{I}$ where \mathbb{I} is a countable infinite set of indices (e.g. a0, t1), and a clause of formulae l_1, \ldots, l_n representing an n-ary disjunction. Steps that are not assumptions are justified by a proof rule \mathcal{R} that depends on a possibly empty set of premises $\{p_1 \ldots p_m\} \subseteq \mathbb{I}$ that only references earlier steps such that the proof forms a directed acyclic graph. A rule might also depend on a list of arguments $[a_1 \ldots a_r]$ where each argument a_i is either a term or a pair (x_i, t_i) where x_i is a variable and t_i is a term. The interpretation of the arguments is rule specific. The context Γ of a step is a list $c_1 \ldots c_l$ where each element c_j is either a variable or a variable-term tuple denoted $x_j \mapsto t_j$. Therefore, steps with a non-empty context contain variables x_j that appear in l_i and will be substituted by t_j . Proof rules R include theory lemmas and resolution, which corresponds to hyper-resolution on ground first-order clauses.

We now have the key components to explain the guiding proof in the bottom part of listing 1.1. The proofs starts with assume steps a0, a1, a2 that restate the assertions from the *input problem* (listing 1.1). Step t1 transforms disjunction into clause by using the Alethe rule or. Steps t2 and t5 are tautologies introduced by the main rule la_generic in Linear Real Arithmetic (LRA) logic and used also in LIA logic, where $\neg l_1, \neg l_2, \ldots, \neg l_n$ represent linear inequalities. These logics use closed linear formulas over the Real signature and Intrespectively. The Real terms in LRA logic are built over the Reals signature from SMT-LIB with free constant symbols, but containing only linear atoms; that is atoms with no occurrences of the function symbols * and /, except in coefficient multiplications—specifically, terms of the form c, (* c x), or (* x c) where x is a free constant and c is an integer or rational coefficient. Similarly, the Int terms in LIA logic are closed formulas built over the Ints signature with free constant symbols, but whose terms are also all linear, such that there is no occurrences of

Rule	Description	
la_generic	Tautologous disjunction of linear inequalities.	
lia generic	Tautologous disjunction of linear integer inequalities.	
la disequality	$t_1 \approx t_2 \vee \neg (t_1 \ge t_2) \vee \neg (t_2 \ge t_1)$	
la_totality	$t_1 \ge t_2 \lor t_2 \ge t_1$	
la tautology	A trivial linear tautology	
la_mult_pos	$t_1 > 0 \land (t_2 \bowtie t_3) \to t_1 * t_2 \bowtie t_1 * t_3 \text{ and } \bowtie \in \{<, >, \ge, \le, =\}$	
la_mult_neg	$t_1 < 0 \land (t_2 \bowtie t_3) \rightarrow t_1 * t_2 \bowtie_{inv} t_1 * t_3$	
la_rw_eq	$(t \approx u) \approx (t \ge u \land u \ge t)$	
div_simplify	Simplification of division.	
prod simplify	Simplification of products.	
unary minus simplify	Simplification of the unuary minus.	
minus_simplify	Simplification of the substractions.	
$sum_simplify$	Simplification of sums.	
comp_simplify	Simplification of arithmetic comparisons.	
Table 1. Linear arithmetic rules in Alethe.		

the function symbols *, /, div, mod, and abs , except terms with coefficients are also allowed, that is, terms of the form c, (* c x), or (* x c) where x is a free constant and c is a term of the form n or (- n) for some numeral n. A linear inequality is of term of the form

$$\sum_{i=0}^{n} c_i \times t_i + d_1 \bowtie \sum_{i=n+1}^{m} c_i \times t_i + d_2$$

$$\tag{1}$$

where $\bowtie \in \{=,<,>,\leq,\geq\}$, where $m \geq n$, c_i,d_1,d_2 are either Int or Real constants, and for each i c_i and t_i have the same sort. Checking the clause validity of t2 and t5 amounts to checking the unsatisfiability of the system of linear equations (we provide more details in section 1.2) e.g. x < 3 and x = 2 in t2. A coefficient for each inequality are pass as arguments e.g. $(\frac{1}{1}, \frac{1}{1})$ in t2. Steps t3 (and t4) applies the **resolution** rule to the premises a1, t2 (respectively t1 t3). Finally, the step t6 concludes the proof by generating the empty clause \perp , concretely denoted as (c1) in listing 1.1. Notice that the contexts Γ of each step are all empty in this proof.

1.2 Linear arithmetic in Alethe

Proofs for linear arithmetic steps use a number of straightforward rules listed in table 1, such as la_totality: $(t_1 \leq t_2 \vee t_2 \geq t_1)$. Simplification rules *_simplify, such as sum_simplify, transform arithmetic formulas by applying equivalence-preserving operations repeatedly until a fixed point is reached; these operations are no more complex than constant folding.

Following our method to encode Alethe described in [6], the linear arithmetic tautology rules la_disequality, la_totality and la_mult_* are encoded as lemmas in our embedding of Alethe in Lambdapi. The simplification

rule comp_simplify is encoded as a lemma for each rewrite case and applied multiple times. We do not support the remaining *_simplify rules and the la_tautology rule in this work, primarily because cvc5 does not follow the Alethe standard for simplification step. Instead, it extends the Alethe format with the RARE simplification rules [10]. As a result, cvc5 did not generate any proofs using these standard rules for the SMT-LIB benchmarks.

A different approach is taken for the primary rules *_generic,as they describe an algorithm. While la_generic rule is primarily intended for LRA logic, it is also applied in LIA proofs when all variables in the (in)equalities are of integer sort. A step of the rule la_generic represents a tautological clause of linear disequalities. It can be checked by showing that the conjunction of the negated disequalities is unsatisfiable. After the application of some strengthening rules, the resulting conjunction is unsatisfiable, even if Int variables are assumed to be Real variables. Although the rule may introduce rational coefficients, they often reduce to integers—as shown in listing 1.1, where the coefficients are $(\frac{1}{1},\frac{1}{1})$. Cases where coefficients cannot be reduced to integers are rare in practice. Let $\varphi_1,\ldots,\varphi_n$ be linear inequalities and a_1,\ldots,a_n rational numbers, then a la_generic step has the general form

$$i. \triangleright \varphi_1, \ldots, \varphi_n$$
 la_generic $[a_1, \ldots, a_n]$

The constants a_i are of sort Real and must be printed using one of the productions $\langle \text{rational} \rangle$ $\langle \text{decimal} \rangle$, $\langle \text{nonpositive_decimal} \rangle$ described in appendix A. To check the unsatisfiability of the negation of $\varphi_1, \ldots, \varphi_n$ one performs the following steps for each literal. For each i, let $\varphi := \varphi_i$, $a := a_i$ and we write $s1 \bowtie s2$ for eq. (1).

- 1. If $\varphi = s_1 > s_2$, then let $\varphi := s_1 \le s_2$. If $\varphi = s_1 \ge s_2$, then let $\varphi := s_1 < s_2$. If $\varphi = s_1 < s_2$, then let $\varphi := s_1 \ge s_2$. If $\varphi = s_1 \le s_2$, then let $\varphi := s_1 > s_2$. This negates the literal.
- 2. If $\varphi = \neg (s_1 \bowtie s_2)$, then let $\varphi := s_1 \bowtie s_2$.
- 3. If $\varphi = s_1 < s_2$, then let $\varphi := -s_1 > -s_2$. If $\varphi = s_1 \le s_2$, then let $\varphi := s_1 \ge -s_2$. We want a canonical form that use only the operators $>, \ge$ and =.
- 4. Replace φ by $\sum_{i=0}^{n} c_i \times t_i \sum_{i=n+1}^{m} c_i \times t_i \bowtie d$ where $d := d_2 d_1$.
- 5. Now φ has the form $s_1 \bowtie d$. If all variables in s_1 are integer sorted: replace $\bowtie d$ according to the table below.

\bowtie	If d is an integer	Otherwise
>	$\geq d+1$	$\geq \lfloor d \rfloor + 1$
\geq	$\geq d$	$\geq \lfloor d \rfloor + 1$

- 6. If all variables of φ are Int and coefficient $a_1 \dots a_n \in \mathbb{Q}$, then $a := a \times lcd(a_1 \dots a_n)$ where lcd is the least common denominator of $[a_1 \dots a_n]$.
- 7. If \bowtie is =, then replace φ by $\sum_{i=0}^{m} a \times c_i \times t_i = a \times d$, otherwise replace it by $\sum_{i=0}^{m} |a| \times c_i \times t_i = |a| \times d$.

Finally, the sum of the resulting literals is trivially contradictory. The sum

$$\sum_{k=1}^{o} \sum_{i=1}^{m^{o}} c_i^k * t_i^k \bowtie \sum_{k=1}^{o} d^k$$

where c_i^k and t_i^k are the constant and term from the literal $varphi_k$, and d^k is the constant d of $varphi_k$. The operator \bowtie is = if all operators are =, > if all are either = or >, and \ge otherwise. The a_i must be such that the sum on the left-hand side is 0 and the right-hand side is > 0 (or \ge 0 if \bowtie is >).

The step 3 has been added by our own, as the subsequent steps in the original algorithm are designed for > and \ge and do not clearly address how to handle < and \le . Additionally, step 6 was added to ensure that our construction is independent of \mathbb{Q} .

Example 1. Consider the la_generic step in the logic QF_UFLIA with the uninterpreted function symbol (f Int):

```
1 (step t11 (cl (not (<= f 0)) (<= (+ 1 (* 4 f)) 1))
2 :rule la_generic :args (1/1 1/4))
```

After step 4, we get $-f>0 \land 4\times f>0$. The step 5 applied and we can strengthen this to $-f\geq 0 \land 4\times f\geq 1$ and after multiplication of the normalized coefficients at step 6, we get $4\times (-f)\geq 0 \land 4\times f\geq 1$. Which sums to the contradiction $0\geq 1$.

The lia_generic is structurally similar to la_generic, but omits the coefficients. Since this rule can introduce a disjunction of arbitrary linear integer inequalities without any additional hints, proof checking is *NP-complete* [12].

2 The approach to reconstruct lia_generic step

The lia_generic represent a challenge for reconstruction because the coefficients are not provided by the solver in the trace i.e. $[a_1 \dots a_r]$ is empty. We decided to leverage the elaboration process of lia_generic performed by Carcara, as doing otherwise would require implementing Fourier-Motzkin elimination for integers, as demonstrated in [11,4] - and therefore reimplementing the work done by the solver.

Carcara considers lia_generic steps as holes in the proof, as "their checking is as hard as solving" [1, §3.2]. However, Carcara relies on an external tool that generates Alethe proofs to formulate the steps by solving corresponding problems in a proof-producing manner. The proof is then imported, and validated before replacing the original step. However, at present, Carcara only use cvc5 for performing this task. In detail, the elaboration method, when encountering a lia_generic step S concluding the negated inequalities $\neg l_1 \lor \ldots \lnot l_n$, generates an SMT-LIB problem asserting $l_1 \land \cdots \land l_n$ and invokes cvc5 on it, expecting an Alethe proof $\pi: (l_1 \land \cdots \land l_n) \to \bot$. Carcara will check this subproof and then replace step S in the original proof by a proof of the form:

```
1 (step S (cl (not l1) ... (not ln)) :rule lia_generic)
```

4

Listing 1.2. Elaboration of lia_generic

In the next section, we first present an overview of our embedding of Alethe in Lambdapi, and then our automatic procedure to reconstruct la_generic step that appear in LIA problem.

3 Reconstruction of la_generic step for LIA logic

3.1 An Overview of Lambdapi

Lambdapi is an implementation of $\lambda\Pi$ modulo theory $(\lambda\Pi/\equiv)$ [7], an extension of the Edinburgh Logical Framework $\lambda\Pi$ [8], a simply typed λ -calculus with dependent types. $\lambda\Pi/\equiv$ adds user-defined higher-order rewrite rules. Its syntax is given by

```
 \begin{array}{ll} \text{Universes} & u ::= \texttt{TYPE} \mid \texttt{KIND} \\ \text{Terms} & t, v, A, B, C ::= c \mid x \mid u \mid \Pi \, x : A, \, B \mid \lambda \, x : A, \, t \mid t \, v \\ \text{Contexts} & \Gamma ::= \langle \rangle \mid \Gamma, x : A \\ \text{Signatures} & \Sigma ::= \langle \rangle \mid \varSigma, c := t : C \mid \varSigma, t \hookrightarrow v \\ \end{array}
```

where c is a constant and x is a variable (ranging over disjoint sets), C is a closed term. Universes are constants used to verify if a type is well-formed – more details can be found in [8, §2.1]. $\Pi x:A.B$ is the dependent product, and we write $A \to B$ when x does not appear free in B, $\lambda x:A.t$ is an abstraction, and t v is an application. A (local) context Γ is a finite sequence of variable declarations x:A introducing variables and their types. A signature Σ representing the global context is a finite sequence of assumptions c:C, indicating that constant c is of type C, definitions c:=t:C, indicating that c has the value t and type t0, and rewrite rules $t \hookrightarrow v$ 1 such that t=c2, where t3 is a constant.

The relation $\hookrightarrow_{\beta\Sigma}$ is generated by β -reduction and by the rewrite rules of Σ . The relation $\hookrightarrow_{\beta\Sigma}^*$ denotes the reflexive and transitive closure of $\hookrightarrow_{\beta\Sigma}$, and the relation $\equiv_{\beta\Sigma}$ (called *conversion*) the reflexive, symmetric, and transitive closure of $\hookrightarrow_{\beta\Sigma}$. The relation $\hookrightarrow_{\beta\Sigma}$ must be confluent, i.e., whenever $t \hookrightarrow_{\beta\Sigma}^* v_1$ and $t \hookrightarrow_{\beta\Sigma}^* v_2$, there exists a term w such that $v_1 \hookrightarrow_{\beta\Sigma}^* w$ and $v_2 \hookrightarrow_{\beta\Sigma}^* w$, and it must preserve typing, i.e., whenever $\Gamma \vdash_{\Sigma} t : A$ and $t \hookrightarrow_{\beta\Sigma} v$ then $\Gamma \vdash_{\Sigma} v : A$ [5].

A Lambdapi typing judgment $\Gamma \vdash_{\Sigma} t : A$ asserts that term t has type A in the context Γ and the signature Σ . The typing rules of $\lambda \Pi / \equiv$ are the one of $\lambda \Pi$ [8, §2], except for the rule (Conv) where it use the version of fig. 1 that identifies types modulo $\equiv_{\beta\Sigma}$ instead of just modulo β -reduction.

$$\frac{\Gamma, \vdash_{\Sigma} B : u \qquad \Gamma \vdash_{\Sigma} t : A \qquad A \equiv_{\beta \Sigma} B}{\Gamma \vdash_{\Sigma} t : B}$$
 (Conv)

Fig. 1. (Conv) rule in $\lambda \Pi / \equiv$

We now provide an overview of the encoding of Alethe linear integers arithmetic in Lambdapi.

3.2 Encoding of Integers in Lambdapi

```
\mathbb{Z}: \mathtt{TYPE}
                                                                                                                        \mathbb{B}: \mathtt{TYPE}
                                        \mathbb{P}: \mathtt{TYPE}
                                                                            Comp: TYPE
| Z0 : Z
                                        | H : ℙ
                                                                           | Eq : Comp
                                                                                                                        | true : B
                                        \mid 0: \mathbb{P} \rightarrow \mathbb{P}
\mid \mathtt{ZPos} : \mathbb{P} 	o \mathbb{Z}
                                                                            Lt: Comp
                                                                                                                        | false : \mathbb{B}
                                       \mid \mathtt{I}: \mathbb{P} \to \mathbb{P}
| ZNeg : \mathbb{P} \to \mathbb{Z}
                                                                            Gt : Comp
int : Set
                                        pos: Set
                                                                            comp: Set
                                                                                                                        bool: Set
El int \hookrightarrow \mathbb{Z}
                                        El pos \hookrightarrow \mathbb{P}
                                                                            E1 comp \hookrightarrow Comp
                                                                                                                        El comp \hookrightarrow \mathbb{B}
```

Fig. 2. Overview of sorts, constructors, constants, and element relations

The definition we use of integers in Lambdapi in fig. 2 follows a common encoding found in many other theories, including the one adopted in the Rocq standard library [13]. First, the type $\mathbb P$ is an inductive type representing strictly positive integers in binary form. Starting from 1 (represented by constructor $\mathbb H$), one can add a new least significant digit via the constructor $\mathbb O$ (digit 0) or constructor $\mathbb I$ (digit 1). The type $\mathbb Z$ is an inductive type representing integers in binary form. An integer is either zero (with constructor $\mathbb Z$ 0) or a strictly positive number $\mathbb Z$ pos (coded as a $\mathbb P$) or a strictly negative number $\mathbb Z$ neg (whose opposite is stored as a $\mathbb P$ value). As discussed in our previous work $\mathbb G$ 1, $\lambda \mathbb H/\mathbb P$ 2 does not support quantify over a variable of type $\mathbb C$ 1. More precisely, it is not possible to assign the type $\mathbb C$ 1 $\mathbb C$ 2. Type, ($\mathbb C$ 3 $\mathbb C$ 4 Prop) $\mathbb C$ 5 Prop to the universal quantifier $\mathbb C$ 4. To address this, we introduce a constant $\mathbb C$ 5 $\mathbb C$ 5 Type for the types

of object-terms, and a constant E1 to embed the terms of type Set into terms of type TYPE giving us the quantifier $\forall: \Pi x: \mathtt{Set}, (\mathtt{E1}\ x \to \mathtt{Prop}) \to \mathtt{Prop}.$ To enable quantification over types such as integers, positive binary numbers, booleans, and comparison results, we introduce a constant of type Set (e.g. int: Set) that represents codes for these types — similar to the Tarski-style universe [9, §Universes], where types are represented by elements of a base type and interpreted via the decoding function. In our setting, the decoding function E1 is realized through a rewriting rule that reduces the term to its corresponding type; for example, E1 int $\hookrightarrow \mathbb{Z}$. The comparison datatype Comp is utilized to define the decidable equality $\dot{=}$ between the \mathbb{Z} and the function cmp for \mathbb{P} (as defined in appendix B).

```
+: \mathbb{Z} \to \mathbb{Z} \to \mathbb{Z}
                                                                                                                                         \doteq: \mathbb{Z} 	o \mathbb{Z} 	o \mathtt{Comp}

The arithmetic operator such as add, sub, and others, as presented in fig. 3 are constants defined by rewriting rules. In the following sections, we will refers

to the rewriting rules for integers as $\to_{\mathbb{Z}}$ and positive binary numbers as $\to_{\mathbb{P}}$. The confluence of the rewriting rules for the arithmetic of \mathbb{Z} and \mathbb{P} has been proven using CSI [14]. A detailed proof of confluence can be found in appendix B.1. The inequality operators for \mathbb{Z} are predicates defined by rewriting rules over the decidable equality \doteq

3.3 Functions used in the translation

We now provide an overview of how input problems expressed in a given SMT-LIB signature [3, §5.2.1] are encoded. In order to avoid a notational clash with the Lambdapi signature Σ , we denote the set of SMT-LIB sorts as $\Theta^{\mathcal{S}}$, the set of function symbols $\Theta^{\mathcal{F}}$, and the set of variables $\Theta^{\mathcal{X}}$. Alethe does not support the sorts Array and String. Moreover, we do not yet provide support for Bitvector and Real. Our translation is based on the following functions:

- $-\mathcal{D}$ translates declarations of sorts and functions in $\Theta^{\mathcal{S}}$ and $\Theta^{\mathcal{F}}$ into constants,
- $-\mathcal{S}$ maps sorts to Σ types,
- \mathcal{E} translates SMT expression to $\lambda \Pi / \equiv$ terms,
- \mathcal{C} translates a list of commands $c_1 \dots c_n$ of the form $i. \Gamma \triangleright \varphi (\mathcal{R} P)[A]$ to typing judgments $\Gamma \vdash_{\Sigma} i := M : N$.

Definition 1 (Function \mathcal{D} translating SMT sort and function symbol declarations). For each sort symbol s with arity n in $\Theta^{\mathcal{S}}$ we create a constant $s: \mathtt{Set} \to \cdots \to \mathtt{Set}$. For each function symbol f σ^+ in $\Theta^{\mathcal{F}}$ we create a constant $f: \mathcal{S}(\sigma^+)$.

In other words, all SMT sorts used in the Alethe proof trace will be defined as constants that inhabit the type Set in the signature context Σ . For every function declared in the SMT prelude, we define a constant whose arity follows the sort declared in the SMT prelude. The translation of sorts is formally defined as follows.

Definition 2 (Function S translating sorts of expression). The definition of S(s) is as follows.

```
- Case s = Bool, then S(s) = El o,

- Case s = Int, then S(s) = El int,

- Case s = \sigma_1 \sigma_2 \dots \sigma_n then S(s) = El(S(\sigma_1) \leadsto \cdots \leadsto S(\sigma_n)),

- otherwise S(s) = El \mathcal{D}(s).
```

Definition 3 (Function \mathcal{E} translating SMT expressions). The definition of $\mathcal{E}(e)$ is as follows.

```
- Case e = (p \ t_1 \ t_2 \dots t_n) and p a logical operator, then \mathcal{E}(e) = \mathcal{E}(t_1) \ p^c \dots p^c \ \mathcal{E}(t_n).

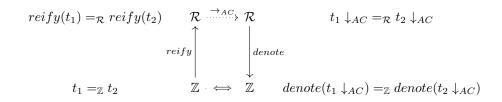

- Case e = (g \ t_1 \dots t_n) with g \in \Theta^{\mathcal{F}}, then \mathcal{E}(e) = (\mathcal{D}(g) \ \mathcal{E}(t_1) \dots \mathcal{E}(t_n)).

- Case e = (\approx \ t_1 \ t_2) then \mathcal{E}(e) = (\mathcal{E}(t_1) = \mathcal{E}(t_2)).

- Case e = (Q \ x_1 : \sigma_1 \dots x_n : \sigma_n \ t) where Q \in \{\text{forall}, \text{exists}\}, then \mathcal{E}(e) = Q^c x_1 : \mathcal{S}(\sigma_1), \dots, Q^c x_n : \mathcal{S}(\sigma_n), \mathcal{E}(t).

- Case e = (x : \sigma) with x \in \Theta^{\mathcal{X}} a sorted variable, then \mathcal{E}(e) = x : \mathcal{S}(\sigma).
```

4 Reconstruction of linear integer arithmetic

Definition 4 (\mathcal{R}) .

$$\begin{array}{c} \operatorname{add} \; (\operatorname{var} \; x \; c_1) \; (\operatorname{var} \; x \; c_2) \hookrightarrow \operatorname{var} \; x \; (c_1 + c_2) \\ \operatorname{add} \; (\operatorname{var} \; x \; c_1) \; (\operatorname{add} \; (\operatorname{var} \; x \; c_2) \; y) \hookrightarrow \operatorname{add} \; (\operatorname{var} \; x \; c_1 + c_2) \; y \\ \operatorname{add} \; (\operatorname{cst} \; c_1) \; (\operatorname{cst} \; c_2) \hookrightarrow (\operatorname{cst} \; c_1 + c_2) \\ \operatorname{add} \; (\operatorname{cst} \; c_1) \; (\operatorname{add} \; (\operatorname{cst} \; c_2) \; y) \hookrightarrow \operatorname{add} \; (\operatorname{cst} \; c_1 + c_2) \; y \\ \operatorname{add} \; (\operatorname{cst} \; 0) \; x \hookrightarrow x \\ \operatorname{add} \; x \; (\operatorname{cst} \; 0) \hookrightarrow x \\ \operatorname{sopp} \; (\operatorname{var} \; x \; c) \hookrightarrow (\operatorname{var} \; x \; (-c)) \\ \operatorname{opp} \; (\operatorname{cst} \; c) \hookrightarrow (\operatorname{cst} \; (-c)) \\ \operatorname{opp} \; \operatorname{opp} \; x \hookrightarrow x \\ \operatorname{opp} \; \operatorname{add} \; x \; y \hookrightarrow \operatorname{add} \; (\operatorname{opp} \; x) \; (\operatorname{opp} \; y) \\ \operatorname{mul} \; k \; (\operatorname{var} \; x \; c) \hookrightarrow (\operatorname{var} \; x \; (k \times c)) \\ \operatorname{mul} \; k \; (\operatorname{add} \; x \; y) \hookrightarrow \operatorname{add} \; (\operatorname{mul} \; k \; x) \; (\operatorname{mul} \; k \; y) \\ \operatorname{mul} \; k \; (\operatorname{cst} \; c) \hookrightarrow (\operatorname{cst} \; k \times c) \\ \operatorname{mul} \; c_1 \; (\operatorname{mul} \; c_2 \; x) \hookrightarrow \operatorname{mul} \; (c_1 \times c_2) \; x \\ \end{array}$$

Definition 5 (reify).

$$\begin{array}{c} \operatorname{reify} \ 0 \hookrightarrow (\operatorname{cst} \ 0) \\ \operatorname{reify} \ (-x) \hookrightarrow \operatorname{opp} \ \operatorname{reify} \ x \\ \operatorname{reify} \ (x+y) \hookrightarrow \operatorname{add} \ \operatorname{reify} \ x \ \operatorname{reify} \ y \\ \operatorname{reify} \ x \hookrightarrow (\operatorname{var} \ x \ 1) \end{array}$$

Definition 6 (denote).

```
\begin{split} \operatorname{den} \; (\operatorname{var} \; c \; x) &\hookrightarrow c \times x \\ \operatorname{den} \; (\operatorname{cst} \; c) &\hookrightarrow c \\ \operatorname{den} \; \operatorname{opp} \; x &\hookrightarrow -(\operatorname{den} \; x) \\ \operatorname{den} \; \operatorname{mul} \; c \; x &\hookrightarrow c \times \operatorname{den} \; x \\ \operatorname{den} \; \operatorname{add} \; x \; y &\hookrightarrow \operatorname{den} \; x + \operatorname{den} \; y \end{split}
```

Definition 7. Let $aliens_{\sqcup}: \mathcal{C} \to \mathcal{C}^+$ be the function mapping every term in \mathcal{C} to a non-empty list of terms such that $aliens_{\sqcup}(t) = aliens_{\sqcup}(u) \circ aliens_{\sqcup}(v)$ if $t = u \sqcup v$, and $aliens_{\sqcup}(t) = [t]$ otherwise.

Conversely, let $comb_{\sqcup} : \mathcal{C}^+ \to \mathcal{C}$ be the function mapping a non-empty list of \mathcal{C} -terms to a term such that $comb_{\sqcup}[t] = t$ and for all $n \geq 2$, $comb_{\sqcup}[t_1, \ldots, t_n] = t_1 \sqcup comb_{\sqcup}[t_2, \ldots, t_n]$.

For example $aliens_{\sqcup}((x \sqcup y) \sqcup z) = [x, y, z]$ and $comb_{\sqcup}[x, y, z] = ((x \sqcup y) \sqcup z)$.

Definition 8 (AC-canonical form). Let \leq be any total order on \mathcal{C} -terms with ϵ the least element such that for all x and b we have $\epsilon <$ (var b x), and (var b x) \leq (var b' y) iff x < y or else x = y and $b \leq b'$ with the order false < true. The AC-canonization of a term t of \mathcal{C} is defined as $[t]_{AC} = comb_{\sqcup}[sort(aliens_{\sqcup}(t))]$, where sort(t) is the list of the elements of t in increasing order with respect to \leq . The relation associating every term t with its AC-canonization $[t]_{AC}$ is denoted \rightarrow AC. Two terms t and t' are AC-equivalent if $[t]_{AC} = [t']_{AC}$. The term t is in AC-canonical form if $t = [t]_{AC}$ and if every strict subterm of t is in AC-canonical form.

Example 2. Assuming that the terms x and y are ordered x < y, the AC-canonical form of XXX is XXX.

Definition 9 (Rewriting modulo AC-canonization). Let $\longrightarrow_{\mathcal{R}}^{AC} = \xrightarrow{AC} \longrightarrow_{\mathcal{R}}$, where \mathcal{R} is defined by the rewrite rules of ??.

An $\longrightarrow_{\mathcal{R}}^{AC}$ step is an AC-canonization followed by a standard $\longrightarrow_{\mathcal{R}}$ step with syntactic matching.

Listing 1.3. Rewriting rule of \mathbb{Z} and \mathbb{P} in the TRS format

16

Lemma 1 (Confluence).

Proof. CSI automatically proves the confluence of $\to_{\mathbb{Z}}$ and $\to_{\mathbb{P}}$ by giving the polynomial interpretation:

$$[\mathit{succ}(x)] = 4*x \qquad [\mathit{add}(x,y)] = 4*x + 4*y + 2 \qquad [\mathit{H}] = 4$$
